

RiskPass

A Simple, Secure Risk Tool for Everyone in Crypto

Free. Secure. Constantly Improving.

Whitepaper v1.0 (Short Edition) — August 2026

“RiskPass helps normal people and institutions understand and manage crypto risk without needing to be experts.”

Read online and get the latest version at stefantsezarov.github.io/riskpass

This is a plain-language summary edition. A longer, fully detailed edition is also available.

1. Executive Summary

Crypto is easy to enter and hard to navigate. Anyone can buy a token in seconds. Almost no one gets a clear answer to the question that matters most: *how risky is this?*

RiskPass answers it. Give it an address — a wallet or a token — and it checks that address against known security indicators, then returns a plain verdict: **PASS, CAUTION, FAIL, or INSUFFICIENT DATA**. Not a price prediction. Not financial advice. A risk read, in seconds, before you act.

Who it's for: newcomers who don't yet know what a “honeypot” is and shouldn't have to; retail traders and small merchants who need a fast check before touching something unfamiliar; institutions who want a transparent risk layer they can verify, not just trust.

Why free, secure, and constantly improving:

- **Free** — the people who need risk information most are often least able to pay for it.
- **Secure** — no private keys, no custody of funds, only public data.
- **Constantly improving** — the risk landscape changes weekly; a static tool goes stale fast.

Most tools are either a bare price chart (too simple to catch anything) or an institutional dashboard (too complex, too expensive). RiskPass sits in between.

2. The Problem: Why Crypto Is Too Risky for Normal People

It's rarely “the market crashed.” More often, it's smaller and preventable:

- A token turns out to be unsellable — built that way from the start.
- A wallet gets connected to a project without understanding what permission was just granted.
- A portfolio sits 90% in one asset, and no one ever showed that number.
- A panic-sell happens because there was no buffer and no plan — just price anxiety.

None of this requires bad luck. It requires the absence of one thing: a clear signal *before* the decision, not an explanation after.

Today's tools don't fill that gap. Price charts show what already happened, not whether a contract can trap funds. Institutional dashboards are often good — but priced and built for professionals, not for someone in their first week.

That gap produces real fear and confusion, and it's why people either panic-sell or ignore real warnings — when every decision feels like a guess, there's no way to tell which reaction fits.

Institutions face a version of the same problem: fragmented data, expensive in-house models, and tools scoped for the biggest players only. A smaller fund is often too sophisticated for consumer tools and too small for enterprise ones.

3. The RiskPass Solution

What it is: a free tool that checks a wallet or token against known risk indicators and returns a clear, conservative verdict — built so a first-time user and a professional can trust the same answer. It's built for humans first: the complexity lives in the engine, not in what you need to understand to use it.

Core principles

- Free to use, no paywall.
- Very secure by design — no custody, no private keys, minimal data collected.
- Constantly improving — detection logic is treated as living work.
- Simple by default, deep on request — one-word headline, full evidence one click away.

What it does for each user

- **Newcomers:** a plain verdict instead of raw data, and a habit — check before you connect or buy.
- **Traders and merchants:** a fast, specific read before acting, with plain-language reasons behind every flag.

- **Institutions:** full evidence behind every verdict, usable as an independent, verifiable cross-check alongside internal models.

RiskPass never gives financial advice. It shows the risk picture; the decision stays yours.

4. How RiskPass Works (User Perspective)

Getting started: no account needed. Paste an address, pick a chain, get an answer.

Connecting wallets: RiskPass only ever reads public, on-chain and provider-side data. It never asks for a private key, seed phrase, or withdrawal permission — no version of it needs those. Future wallet-connection convenience features will follow the same rule: read-only, always.

The result shows four things: a verdict, a one-sentence plain-language reason, a coverage line (for example, “17 of 18 checks completed”), and the full checklist behind it.

A PASS means *no major risk indicators were found among the checks performed* — not that none exist anywhere. When too little reliable data comes back, RiskPass says so directly: **INSUFFICIENT DATA**, never a quiet default to a clean-looking result. A confirmed, high-severity finding always overrides everything else, even a mostly-empty scan. Uncertainty is never allowed to look like safety.

Example results: “A confirmed high-severity indicator was detected” means stop and look closer. “Only 4 of 18 indicators returned usable data” is an honest shrug, not a clean bill of health. What you do with the read is up to you.

RiskPass updates regularly as scam patterns and chains evolve, tested against a standing set of adversarial cases before every release.

5. Technical Architecture

```
User --> Frontend --> Chain Adapter --> Verdict Engine --> Result
                        ^
                        |
                External security data provider
```

Frontend renders results; it never decides them. Classification logic lives entirely beneath it.

Chain adapters exist because chains work differently — an EVM contract’s “mint function” and a Solana token’s “mint authority” are related but distinct mechanisms, checked through different data. Each adapter validates that chain’s address format, fetches data via a read-only API call, and translates the response into RiskPass’s

internal format. Adding a chain means writing a new adapter, not touching the decision logic.

Data sources: RiskPass aggregates from established providers rather than building its own intelligence from scratch — currently GoPlus Security's public APIs, covering EVM chains and Solana. The architecture supports more than one provider per chain over time, so no single source becomes the sole “truth.”

Data flow: an address goes from your browser to the provider, gets evaluated, and the result comes back. No account is required to scan, and addresses aren't logged or stored.

The verdict engine decides PASS / CAUTION / FAIL / INSUFFICIENT DATA and knows nothing about any specific chain or provider — only a list of checks, each *clear*, *flagged*, or *unreadable*. Its priority order, in short:

- 1 One confirmed, high-severity finding always means **FAIL** — regardless of how sparse the rest of the data is.
- 2 Too little usable data means **INSUFFICIENT DATA**, not PASS.
- 3 Above that threshold, accumulated indicators decide FAIL or CAUTION.
- 4 Only adequate coverage *and* nothing concerning produces **PASS** — and a missing high-severity check gets disclosed even then.

The core commitment: **absence of evidence is never treated as evidence of safety.**

Security model: no custody, no private keys, encrypted connections, minimal data retention, and every external response treated as untrusted input.

6. Risk Models and Metrics

Contract and wallet security risk — *live today.*

Before you interact with a token or address, RiskPass checks known red flags: can the contract block selling, can the owner alter balances, is the address linked to known scams. Some findings are decisive alone — a confirmed honeypot means FAIL regardless of anything else. Others accumulate toward CAUTION.

Portfolio concentration risk — *roadmap.*

If too much sits in one asset, one bad outcome becomes a portfolio-wide one. Planned measurement: share held in the largest position, and the largest three, as a plain percentage.

Volatility risk — *roadmap.*

Some assets swing hard. Unpreparedness, not the swing itself, is what turns a dip into a panic-driven loss.

Stablecoin and buffer risk — *roadmap.*

Holding some low-volatility assets turns “the market dropped” from an emergency into a wait.

Protocol and smart contract risk — *live today, expanding.*

Newer or less-scrutinized protocols get flagged specifically — a risk category most newcomers have no way to judge on their own.

Behavioral risk signals — *roadmap.*

Patterns like very frequent trading or repeated interaction with brand-new contracts correlate with worse outcomes. Framed as information about a pattern, never judgment of a person.

These are tools for understanding, built on real data — never a crystal ball.

7. Security and Trust

- **No custody, ever.** There's nothing to steal because nothing is held — not a disabled feature, a nonexistent capability.
- **Read-only, always.** Every connection, including future wallet features, can view but never move or spend.
- **Encryption in transit and at rest,** with security review as an ongoing practice, not a one-time checkbox.
- **Transparency.** Changes are documented, incidents are communicated plainly, and feedback channels stay open.

RiskPass won't claim to be unhackable — no honest tool does. What it commits to is specific: no custody, no keys, minimal data, untrusted-input handling by default, and a verdict engine built to fail toward caution rather than false confidence. A tool that quietly turns uncertainty into a clean PASS is arguably worse than no tool at all.

Being free isn't just pricing — broad usage is what surfaces the edge cases that make the tool better. Every update is tested against a growing set of adversarial cases before it ships.

8. Roadmap and Continuous Improvement

Near-term (6–12 months): broader chain coverage, added one tested adapter at a time; portfolio-level metrics on top of the existing engine; deeper in-app explanations; optional read-only wallet connections; a mobile experience once the web core is proven; early institutional exports and API access.

Long-term: RiskPass as a simple risk layer other tools build on — wallets, tax software, portfolio trackers integrating checks rather than building their own.

Community: feature requests, bug reports, and disagreements with a verdict are all useful signal. Some components, starting with the verdict engine's logic, may be open-sourced over time.

Through all of it: free, secure, constantly improving.

9. Use Cases and Stories

Maya, a newcomer pastes a friend-recommended token's contract into RiskPass before connecting her wallet. FAIL — a confirmed honeypot. She never connects. No dramatic story, just a loss that didn't happen.

Devon, a retail trader checks his holdings on a whim and finds three of five positions share unverified source code and an upgradeable proxy. He doesn't panic-sell — he stops adding to those positions and diversifies elsewhere.

Priya, a small merchant periodically checks the tokens her shop holds and catches CAUTION-level indicators on one — an upgradable transfer fee. She converts to stablecoins the same day.

An analyst at a small fund uses RiskPass as an independent second opinion during due diligence. When it disagrees with the fund's internal model, that disagreement itself prompts a closer look before capital moves.

10. Limitations and Responsible Use

RiskPass does not guarantee profits, predict prices, replace professional advice, or catch every possible risk — detection is built on known patterns, and those have limits.

RiskPass does provide an honest read on known indicators, surface exposures a user might miss, and support better-informed decisions — the decision itself always stays with the user.

Use it as one input, not the only one. Crypto carries real risk no tool can fully remove. Being direct about that isn't a weakness — it's the reason the verdict is worth trusting at all.

11. Glossary

Wallet

Holds the keys controlling your crypto; lets you send, receive, or interact with it.

Private key

A secret that proves ownership and moves funds. Never share it — not with RiskPass, not with anyone.

Stablecoin

A crypto asset designed to hold a steady value, usually pegged to a currency like the dollar.

Volatility

How much and how fast an asset's price moves.

Smart contract

Self-executing code on a blockchain that defines how a token or app behaves.

API key

A credential letting a service make requests on your behalf. RiskPass only ever uses read-only ones.

Read-only access

Permission to view, never to change, move, or spend.

Honeypot

A token built so it can be bought but not sold.

Mint authority / mint function

The ability to create new supply after launch. Not automatically dangerous — worth knowing regardless.

12. Closing: The RiskPass Promise

Crypto doesn't need to be less powerful to be safer. It needs a better signal before the moments that matter — before a connection, a trade, a transfer. That's the job.

Free, because clear risk information shouldn't be gated behind a price. **Secure**, because a tool meant to protect people has to start by not becoming a risk itself. **Constantly improving**, because a static defense against a moving landscape stops being a defense.

If you use RiskPass, disagree with a verdict, or find something it missed — that's not a complaint, it's exactly what makes the next version better.

This whitepaper is a living document. It will evolve as RiskPass evolves.
